(54) Seal tab for a metal-air electrochemical cell.

(57) A seal tab consisting of an acrylic adhesive applied to a biaxially-oriented three-ply synthetic paper of polypropylene is used as a sealing means for metal-air electrochemical cells, and batteries constructed thereof. The seal tabs prevent loss of rate capability and capacity due to interactions with the surrounding environment prior to the placement into service of metal air cells, yet without so isolating the cells such that the initial open circuit voltage is deemed unacceptable by the end user. Additionally, the seal tab, as provided, is easily and cleanly removed, which enhances the cell's consumer appeal.

EP 0 230 039 A2

SEAL TAB FOR A METAL-AIR ELECTROCHEMICAL CELLFIELD OF INVENTION

This invention pertains generally to metal-air electrochemical cells and batteries constructed thereof, and more particularly to an improved sealing means for such cells which prevents the loss of rate capability and capacity due to interactions with the surrounding environment between the time such cells are manufactured and when they are placed into service.

BACKGROUND OF THE INVENTION

Metal-air electrochemical cells, especially those wherein the metal is powdered zinc, have become increasingly popular power sources for small electrical devices. Metal-air cells have an inherent advantage over most other electrochemical cell systems in that for a given cell volume, metal-air cells have a greater capacity. The greater capacity is due to the fact that in metal-air electrochemical systems, oxygen from the atmosphere, which is essentially limitless, is the active cathode material. Hence, metal-air electrochemical cells do not contain consumable cathode material and, therefore, can contain a greater amount of anodic material. It is this increase in the amount of anodic material which leads to the increased, per unit volume, capacity of metal-air cells. Due to their high capacity and relatively flat discharge curve, metal-air cells are particularly adapted for use in those applications which require moderate drains and continuous discharge usage.

In metal-air cells, air containing oxygen, the cathodic reagent, enters the cell through port(s) in the cell can which are immediately adjacent to a cathode assembly. The air diffuses into an air cathode subassembly where the oxygen

1 is reacted. This air cathode subassembly generally consists of  
2 mixtures of activating chemicals supported by a complex  
3 physical structure. The air cathode subassembly also slows the  
4 rate of diffusion of other gases, particularly carbon dioxide  
5 and water vapor, through the electrode to the reaction site.  
6 These gases in air, particularly water vapor, can have a  
7 profound limiting effect on the capacity of the cell.

8 Once the oxygen has entered the cell, it diffuses  
9 through a separator, which is a moisture barrier usually of a  
10 plastic-like material impervious to liquids such as the  
11 alkaline electrolyte, and reacts with the water in the  
12 electrolyte. This reaction consumes electrons and produces  
13 hydroxide ions which, after migrating into the anode chamber,  
14 oxidize the metal anode, generally producing two electrons for  
15 each atom of the metal reacted. Electrochemical cells  
16 comprised of metal anodes and air cathodes are well known, and  
17 are more fully discussed in references such as U.S. - A -

18 3,149,900

and 3,276,909

19 A major problem associated with metal-air  
20 electrochemical cells is the loss of cell capacity as a result  
21 of storage, shipping, etc. of the cell between the time the  
22 cell is manufactured and the time the cell is used as a source  
23 of electrical power. Another often-noticed limitation is the  
24 depressed open circuit voltage of such cells upon placement  
25 into service after storage, often of only a few weeks duration.  
26 The problems and limitations observed with metal-air  
27 electrochemical cells stem from the same factor which provides  
28 for their capacity advantage: interaction with the  
29 environment. Since the diffusion of oxygen into the cells  
30 begins a series of reactions which ultimately consume the

1 anodic material, it is readily apparent that a significant  
2 ingress of oxygen into a metal-air electrochemical cell during  
3 storage will significantly reduce a cell's capacity, therefore  
4 reducing the viable shelf life for such an electrochemical  
5 cell. However, the ingress or egress of water vapor during  
6 storage can have an even more dramatic effect on the  
7 performance of metal-air cells after storage of even a few  
8 months.

9 Water is present in metal-air electrochemical cells  
10 since the electrolytes in such cells are aqueous alkaline  
11 solutions. And since the water in the electrolyte is directly  
12 involved in the reactions which produce the electric energy,  
13 any reduction in the water content of the cell due to the  
14 egress of water vapor attributable to a lower relative humidity  
15 in the external cell environment will decrease the reaction  
16 rate, i.e., the production of electrons. Such a decrease in  
17 the reaction rate necessarily reduces the rate capability and  
18 capacity of the cell. The ingress of water vapor, due to a  
19 higher relative humidity outside of the cell can have a similar  
20 deleterious effect on cell performance, since the cell becomes  
21 overfilled with water. The excess of water causes the  
22 premature conclusion of the electrochemical reactions and  
23 substantially reduces the rate capability of the cell.

24 In order to diminish the deleterious effects of the  
25 environment on metal-air cells, the air entry ports of metal-  
26 air cells are normally sealed with removable tabs (or tapes)  
27 upon manufacture. The removal of such a seal tab when a cell  
28 is placed in service theoretically ensures that the freshly  
29 unsealed cell has the approximate capacity of a freshly  
30 manufactured cell. Unfortunately, such theoretical fresh cell

1 capacity has been difficult to consistently obtain, since the  
2 sealing means heretofore commercially used in the manufacture  
3 of metal-air cells have been unable to eliminate the recognized  
4 effects of the environment which occur during the storage of  
5 metal-air cells.

6 Presently, the air entry ports of most metal-air  
7 cells are sealed upon manufacture by tabs consisting of rubber  
8 based adhesives applied to a rubber impregnated paper face  
9 stock and overlaid with a polyester film. Metal-air cells  
10 sealed with such tabs display substantial reductions in cell  
11 capacity upon being placed into service as a source of  
12 electrical power after storage. Moreover, such cell tabs  
13 exhibit tape delamination, i.e., upon storage for long periods  
14 of time and/or at elevated temperatures, the strength of  
15 adhesive-to-cell case bond increases to the point where it  
16 exceeds the cohesive strength of the paper. When this  
17 phenomena occurs, upon removal of the tab, the adhesive and a  
18 layer of paper often remain on the cell case. Along with a  
19 decrease in cosmetic appeal, such cells often cannot be fully  
20 activated and may insulate the cell from electrical contact,  
21 thereby allowing for the possible perceived failure of the cell  
22 by the consumer.

23 Another type of cell sealing means, which uses  
24 rubber-based adhesives applied directly to polyester film, have  
25 been utilized to prevent the loss of cell capacity during  
26 storage of the unused cells. Such impervious tapes are quite  
27 effective in sealing off the cell from the environment.  
28 However, upon only a few weeks storage, the voltage of a  
29 metal-air electrochemical cell sealed with such a tape drops to  
30 the voltage of the metal-carbon couple, which for metal-air

1 cells having a powdered zinc anode is 0.4 volts. This low  
2 voltage results from the insufficient ingress of oxygen to  
3 maintain the cell voltage. A consumer, upon removing such a  
4 tape from a metal-air cell may have to wait a considerable time  
5 before the functional voltage is re-established. In some  
6 cases, a consumer may perceive that the cell is defective.

7 Because of the aforementioned advantages of metal-air  
8 electrochemical cells, it is imperative that the environmental  
9 effects heretofore incumbent with the storage of metal-air  
10 cells be eliminated, without so isolating the cell from the  
11 environment such that the open circuit voltage upon placing  
12 the cell in service is unacceptable. Therefore, it is an  
13 objective of the present invention to provide a removable seal  
14 for a metal-air electrochemical cell which allows for the  
15 storage of such cells without the attendant decrease in cell  
16 performance.

17 Another objective of the present invention is to  
18 provide a removable seal for a metal-air electrochemical cell  
19 which reduces the diffusion of water vapor into or out of such  
20 cells during storage even under dry conditions at elevated  
21 temperatures.

22 Another objective of the present invention is to  
23 provide a removable seal for a metal-air electrochemical cell  
24 which allows the open circuit voltage of such cells upon  
25 placement in use after storage to have a functional open  
26 circuit voltage upon removal of the tab.

27  
28  
29 SUMMARY OF THE INVENTION

30 The objectives of the present invention are achieved

by covering the air entry ports of metal-air electrochemical cells with a slightly permeable, easily removable three component seal tab. The seal tab of the present invention consists of a biaxially-oriented three-ply synthetic paper of polypropylene to which a removable acrylic polyacrylate adhesive is applied. The bond formed between the acrylic adhesive and the metal face of a metal-air electrochemical cell is weaker than the adhesive to polypropylene paper bond and the cohesive strength of the polypropylene paper. To provide additional protection from the environment, the exposed polypropylene paper surface is covered by a plastic film. A seal tab constructed according to the present invention and applied during manufacture of metal-air electrochemical cells greatly improves the post-storage performance of such cells vis-a-vis cells manufactured and stored with the removable cell tabs of the prior art.

BRIEF DESCRIPTION OF THE DRAWINGS

FIG. 1 is a graph comparing the amount of water egress with time from zinc-air button cells manufactured and stored with removable seal tabs of the present invention and such cells sealed with the removable seal tabs of the prior art.

FIG. 2 is a graph comparing the amount of water egress with time from zinc-air button cells manufactured and stored with removable seal tabs of the present invention and such cells sealed with the removable seal tabs of the prior art, wherein the seal tabs were initially applied to the cells at elevated temperatures.

FIG. 3 is a graph comparing, after storage for 12 weeks under hot, dry conditions, the open circuit voltage of zinc-air button cells manufactured and stored with removable

1 seal tabs of the present invention and such cells sealed with  
2 the removable seal tabs of the prior art.

3 DESCRIPTION OF THE INVENTION

4 While the present invention is applicable to, and can  
5 be used in conjunction with, all types of metal-air  
6 electrochemical cells and batteries comprised of such cells,  
7 the drawings depict the results of the preferred embodiment  
8 herein described, i.e., a zinc-air button cell.

9 In general, the present invention comprises a  
10 seal tab for metal-air electrochemical cells, consisting of a  
11 three component material which, when made and used according to  
12 the teachings described herein, prevents the marked decrease in  
13 the rate capability and capacity of metal-air electrochemical  
14 cells which have been subject to post-manufacture storage under  
15 various conditions. The base material, i.e., the face stock of  
16 the seal tab of the present invention is a biaxially-oriented  
17 three-ply synthetic paper of polypropylene, such as SYNTIQUE<sup>®</sup>  
18 manufactured and marketed by Avery International. While this  
19 face stock material should be between 68.6  $\mu\text{m}$  (2.7 mils) and 94  $\mu\text{m}$  (3.7  
20 mils) in thickness, the inventors prefer that the polypropylene paper be  
21 81.9  $\mu\text{m}$  (3.2 mils) ( $\pm 10\%$ ) in thickness.

22 The material which forms the seal with the surface of  
23 the metal-air electrochemical cell is a clear acrylic adhesive,  
24 which has been applied to one side of the face stock. The  
25 thickness of the adhesive can vary from 12.7  $\mu\text{m}$  (0.5 mils) to 25  $\mu\text{m}$   
26 (1.0 mils), with 17.8  $\mu\text{m}$  (0.7 mils) being preferred by the inventors.

27 The opposite side of the polypropylene paper face  
28 stock is covered with a plastic film to further lessen the  
29 observed environmental effects on the performance of metal-air  
30 cells after storage. The plastic film can be made of either

1 polyester, approximately 28.1  $\mu\text{m}$  (1.5 mils) thick, or acetate,  
2 approximately 50.8  $\mu\text{m}$  (2.0 mils) thick.

3 The three component seal tab of the present invention  
4 is applied by mechanical means to the face of the metal-air  
5 electrochemical cell which contains the air entry ports. Since  
6 various materials may be used as the metal-air electrochemical  
7 cell (or battery) container, the acrylic adhesive, which  
8 contacts the cell container must display high initial tack, but  
9 still be easily removed, from a wide variety of metallic and  
10 non-metallic surfaces. While the seal tab of the present  
11 invention may be applied to the metal-air electrochemical cell  
12 at room temperature, the inventors prefer to apply the seal tab  
13 at elevated temperatures, preferably at 93°C (200°F).

14 The seal tab of the present invention does not  
15 display tape delamination, even if the metal-air cells are  
16 stored for several months at elevated temperatures. With seal  
17 tabs of the present invention, the bond formed between acrylic  
18 adhesive and the surface of the metal-air electrochemical cell  
19 is much weaker than both the bond between the polypropylene  
20 face stock and the acrylic adhesive and the cohesive strength  
21 of the face stock itself. A characteristic of the  
22 acrylic adhesive when used in the present invention is that the  
23 strength of the bond between it and the metal-air cell  
24 container does not significantly increase with time and/or  
25 temperature.

26 Seal tabs of the present invention allow for  
27 different rates of transport of the various gases into and out  
28 of the metal-air electrochemical cells. While the present  
29 invention allows the ingress of enough oxygen such that the  
30 open circuit voltage of the metal-air electrochemical cell is

functional even after several months storage, it reduces appreciably the ingress or egress of water vapor.

EXPERIMENTAL RESULTS

In order to quantify the magnitude of the benefits of the present invention, comparative tests of identical zinc-air button cells stored for various periods of time under various conditions were conducted. "Control" cells are zinc-air button cells whose air entry ports were sealed during storage by seal tabs of the standard, commercial construction, i.e., a rubber impregnated paper containing a rubber-based adhesive and a polyester film. "Lot A" cells are zinc-air button cells whose air entry ports were sealed during storage by seal tabs of the present invention wherein the plastic film was acetate. "Lot P" cells are zinc-air button cells whose air entry ports were sealed during storage by seal tabs of the present invention wherein the plastic film was polyester. The seal tabs of the "Control", "Lot A" and "Lot P" cells were initially affixed to the cells at room temperature. "Control-1" cells, "Lot A-1" cells and "Lot P-1" cells are "Control", "Lot A" and "Lot P" cells, respectively, wherein the seal tabs were initially affixed to the cells at 93°C (200°F).

Test 1:

To determine how much water diffuses through the various seal tabs, zinc-air button cells were weighed once a week, for 12 weeks while being stored at 55°C (130°F). Any reduction in cell weight was attributed to the egress of water vapor, since any diffusion of oxygen would have increased cell weight. The results of this test, graphed in Figures 1 and 2, clearly demonstrate that seal tabs of the present invention are approximately twice as effective as those of the prior art in

preventing the egress of water vapor and that seal tabs applied at 93°C (200°F) are more effective in preventing the egress of water vapor than such tabs applied at room temperature.

Test 2:

To determine the effects on cell capacity of the seal tabs, the capacity of the zinc-air button cells were measured under a continuous 1500-ohm drain to both 1.1V and 0.9V after being stored for 8 weeks at 55°C (130°F). These capacities were then compared with those of freshly manufactured zinc-air button cells. The results of this test, which are shown in Table I, clearly indicate that when seal tabs are applied to zinc-air button cells, seal tabs made according to the present invention eliminate at least 75% of the reduction in cell capacity displayed in cells sealed with the prior art seal tabs.

TABLE I: CELL CAPACITY\* AFTER  
8 WEEKS STORAGE\*\* AT (130°F) 55°C

	mAh		% LOSS	
	1.1V	0.9V	1.1V	0.9V
Control	104.2	105.2	-13.0	-12.7
Lot A	118.5	119.5	- 1.1	- .8
Lot P	117.0	118.0	- 2.3	- 2.0

\* At 1500-ohm continuous load

\*\* Prior to storage, zinc-air button cell capacities were:  
119.8 mAh to 1.1V  
120.4 mAh to 0.9V

Test 3:

To determine the effect upon open circuit voltage, the open circuit voltage of the zinc-air button cells was initially determined. The cells were then stored at 55°C (130°F) for a total of 12 weeks. After the 4, 8 and 12 weeks, the open circuit voltage for each cell was determined.

0 230 039

The results of this test, which are displayed in Table II, clearly indicate that the present invention allows the open circuit voltage of the button cells to remain at functional levels, while the prior art seal tabs often allow the open circuit voltage to drop below functional levels.

TABLE II: CELL VOLTAGE AT (130°F) 55°C

	<u>At 0 Weeks</u>		<u>At 4 Weeks</u>		<u>At 8 Weeks</u>		<u>At 12 Weeks</u>	
	OCV	%Fail	OCV	%Fail	OCV	%Fail	OCV	%Fail
Control	1.050	22.0	0.986	22.0	1.039	27.0	1.022	23.0
Control-1	1.182	2.5	0.980	20.0	0.944	44.0	0.935	43.0
Lot A	1.259	0.0	1.210	0.0	1.237	0.0	1.244	0.0
Lot A-1	1.263	0.0	1.203	2.5	1.232	0.0	1.254	0.0
Lot P	1.224	2.5	1.196	2.5	1.195	2.9	1.224	3.6
Lot P-1	1.196	5.0	1.211	0.0	1.234	0.0	1.242	0.0

Note: %Fail is percentage of cells with OCV below 0.9V.

Additionally, Test 3 showed that after 12 weeks the present invention allows one to predict the range of the open circuit voltage of zinc-air button cells, while prior art seal tabs allow a wide variance in the open circuit voltage. The range of the open circuit voltage for zinc-air button cells sealed with various tabs is graphed in Figure 3.

What is claimed is:

1. An only slightly permeable, removable seal tab, having high initial tack, used to cover the air entry ports of a metal-air electrochemical cell between the time said cell is manufactured and the time said cell is used as a source of electrical power, which comprises a face stock of biaxially-oriented three-ply polypropylene paper interposed between an acrylic adhesive and a plastic film.

2. The seal tab as in claim 1, wherein the thickness of said face stock is between 68.6 and 94  $\mu\text{m}$ , preferably is between 12.7 to 25.4  $\mu\text{m}$ , more preferably is about 17.8  $\mu\text{m}$ .

3. The seal tab as in claim 1 or 2, wherein the plastic film is selected from polyester film and acetate film.

4. The seal tab as in claim 3, wherein the plastic film is an acetate film between 44.4 and 57.1  $\mu\text{m}$  thick.

5. The seal tab as in claim 3, wherein the plastic film is a polyester film between 31.7 and 44.4  $\mu\text{m}$  thick.

6. A metal-air electrochemical cell wherein a seal tab according to claim 1 to 5 has been mechanically affixed to the cell in such a manner as to cover the air entry port or ports of the cell.

7. The metal-air electrochemical cell of claim 6, wherein the seal tab has been mechanically affixed to the cell

**0 230 039**

at an elevated temperature, preferably at about 93°C. .

8. The metal-air electrochemical cell as in claim 6 or 7, wherein the cell is a zinc-air cell, especially a button cell.
